

Descriptive Analytics Report — Zepto Sales

Product-Level Demand, Revenue, Discounting & Influencer-Marketing Performance Across Six Cities

CONTENTS

1. Objective
 2. How This Would Work at Real Scale
 3. Market Context: Zepto's Position in India's Quick-Commerce Market
 4. Product Ranking by Orders
 5. Product Ranking by Revenue
 6. Category-Wise Performance
 7. City-Wise (Regional) Performance
 8. City × Category Demand Matrix
 9. Discount Impact Analysis
 10. Influencer-Marketing Impact
 11. Pricing & Average Order Value (AOV) Analysis
 12. Top & Bottom Performing Product–City Pairs
 13. Data Quality Notes & Limitations
 14. Summary of Key Metrics
 15. Descriptive → Predictive: Suggested Next Steps
- Appendix: Glossary

Note: This report is built entirely from the supplied zepto_sales_dataset.csv — 300 aggregated product , city records covering 10 SKUs across 6 categories (Snacks, Grocery, Beverages, Dairy, Instant Food, Confectionery) and 6 metro cities (Delhi, Mumbai, Bangalore, Chennai, Hyderabad, Pune). The dataset is a cross-sectional snapshot (no date/time field), not a day-by-day time series, so every insight below is a same-period comparison across products, cities and categories rather than a trend-over-time view.

1. Objective

- Which products and categories are driving order volume and revenue for Zepto today?
- Which cities show the strongest demand, and how does that demand break down by category?
- Does discounting actually move order volume, or is the relationship weaker than assumed?
- Does influencer activation correlate with higher orders/revenue in this dataset?
- Where do pricing and average order value diverge across categories, and what does that imply for margin?

2. How This Would Work at Real Scale

- Zepto's model is 10-minute delivery, so "descriptive analytics" in production is really a low-latency operational system, not an overnight report. A realistic architecture:

Layer	Purpose	Typical tools
Investigation	Capture each order event from the app/dark-store at the moment it's placed	Python, Excel, Data Visualization
Stream processing	Roll up raw events into per-product, per-city, per-hour aggregates	Claude
Storage	Hold raw events (audit) and pre-aggregated tables (speed)	SQL
Batch aggregation	Hourly/nightly rollups: sales by SKU/city, discount performance, campaign tagging	Python,Google
Serving / BI layer	Dashboards refreshed near-real-time for dark-store ops, hourly for category teams	Data Visualization

- The tables below reflect the output of that pipeline — aggregated by product and city — not raw order-level events.

3. Market Context: Zepto's Position in India's Quick-Commerce Market

Zepto operates in India's quick-commerce (10–30 minute delivery) space alongside Blinkit and Swiggy Instamart. Public market-share estimates in 2026 place Blinkit as the clear leader at roughly 45–50% of the category, with Zepto and Swiggy Instamart each holding a mid-20% share, though estimates vary by source depending on whether they weight by GMV or order volume.

Zepto is widely cited as differentiating on delivery speed and premium user experience, with a comparatively young, urban customer base and — per industry commentary — a stronger-than-peers average order value, even as the company continues to prioritize growth and network expansion (300+ dark stores) over near-term profitability. This context matters for reading the dataset below: category mix (staples vs. discretionary snacks/beverages) and city-level demand concentration are exactly the levers a quick-commerce player uses to defend share against a larger competitor.

4. Product Ranking by Orders

Ranking all 10 products by total orders summed across every city:

The Product Ranking by Orders ranks all 10 products according to their total number of orders across all cities. The chart provides a clear view of which products have the highest and lowest customer demand.

Key Insights

1. **Coca Cola 1L is the most ordered product**, with **6,175 total orders**, making it the clear leader in terms of customer demand.
2. **Parle-G ranks second** with **5,789 orders**, followed by **Maggi Noodles** with **5,654 orders**. Both products show strong and consistent demand.
3. **Nestle Munch** occupies the fourth position with **5,243 orders**, indicating that packaged snacks also contribute significantly to overall order volume.
4. **Aashirvaad Atta** recorded **5,121 orders**, placing it fifth. Its position suggests that essential grocery products have substantial demand on the platform.
5. **Amul Milk 500ml** generated **4,902 orders**, ranking sixth. Although lower than the top five products, it still maintains a relatively high order volume.
6. **Pepsi 500ml** recorded **4,627 orders**, followed by **Oreo Biscuits** with **4,469 orders**. These products show moderate but healthy demand.
7. **Fortune Oil 1L** and **Britannia Cake** are the two lowest-ranked products, with **4,318** and **4,148 orders**, respectively.
8. The difference between the **highest-ranked product (Coca Cola 1L)** and the **lowest-ranked product (Britannia Cake)** is **2,027 orders**. This indicates a noticeable difference in product popularity.
9. **Six products have more than 4,900 orders**, showing that demand is relatively strong across most products rather than being concentrated in only one or two items.

10. Overall, **beverages, packaged foods, snacks, and essential grocery products** all appear among the top-performing products, suggesting that customers place orders across a diverse range of everyday-consumption categories.

Overall Interpretation

The chart indicates that **Coca Cola 1L is the strongest-performing product by order volume**, while **Britannia Cake has the lowest order count among the listed products**. The relatively high order volumes across most products indicate **healthy and diversified customer demand**. The business can focus on maintaining adequate inventory for high-demand products such as Coca Cola 1L, Parle-G, and Maggi Noodles, while analyzing the comparatively lower performance of Fortune Oil 1L and Britannia Cake to identify opportunities for **promotions, pricing adjustments, or improved visibility**.

Key Findings

The Product Leaderboard shows that Coca Cola 1L leads the market with **6,175** orders, followed by Parle-G and Maggi Noodles. Most products recorded more than **4,000** orders, indicating strong overall customer demand. The **2,027-order gap** between the highest and lowest products highlights differences in product popularity. The findings can help the business prioritize inventory, marketing, and promotional strategies for high- and low-performing products.

KPI: Total orders

Value: 50,448

Usage: Shows the total orders generated by all 10 products

Interpretation: The 10 products collectively received 50,448 orders, indicating strong overall demand.

KPI: Top vs Bottom Order Ratio

Value: 1.49x

Usage: Compares the strongest and weakest Products.

Interpretation: Coca Cola 1L receives about 1.49 times as many orders as Britannia Cake.

5. Product Ranking by Revenue

Re-ranking the same 10 products by total revenue inverts part of the order-count picture:

The **Product Ranking by Revenue** ranks the 10 products according to the total revenue generated across all cities. Unlike the order-based ranking, this chart highlights the products that contribute the most to the business's overall sales value.

Key Insights

1. **Coca Cola 1L is the highest revenue-generating product**, generating approximately **₹714,681** in total revenue. It holds the top position and is also the most ordered product, indicating both strong demand and strong revenue contribution.
2. **Maggi Noodles ranks second** with revenue of approximately **₹661,477**. Interestingly, Maggi moves up from third place in the order-based ranking, showing that it generates relatively higher revenue per order compared with some competing products.
3. **Parle-G ranks third**, generating around **₹658,853**. Although it had the second-highest number of orders, it falls to third position in revenue, suggesting a comparatively lower revenue contribution per order.
4. **Nestle Munch** generated approximately **₹647,424**, ranking fourth. Its strong position indicates that the product contributes significantly to total sales despite not being among the top three by order volume.
5. **Amul Milk 500ml** generated about **₹579,648**, placing it fifth. This reflects strong demand for essential grocery products and a substantial contribution to overall revenue.
6. **Oreo Biscuits** generated approximately **₹533,104**, ranking sixth. Its revenue performance is moderate compared with the leading products.
7. **Britannia Cake** generated around **₹520,490**, placing seventh. Although it has one of the lowest order counts, its revenue ranking is higher than its order ranking, suggesting a relatively higher value per order.

8. **Pepsi 500ml** generated approximately **₹512,321**, ranking eighth. Despite having more orders than some products, it generates comparatively lower total revenue.
9. **Aashirvaad Atta** generated around **₹497,163**, ranking ninth. This is a notable shift from its fifth position in the order-based leaderboard, indicating that its high order volume does not translate into equally high total revenue.
10. **Fortune Oil 1L** has the **lowest total revenue**, at approximately **₹458,190**. It also ranks near the bottom in terms of orders, making it one of the weaker-performing products overall.

Overall Interpretation

The chart shows that high order volume does not always result in the highest revenue. For example, Aashirvaad Atta ranks fifth by orders but ninth by revenue, whereas Britannia Cake ranks tenth by orders but seventh by revenue. This suggests differences in the average value generated per order for different products.

Coca Cola 1L stands out as the strongest product, leading both order volume and revenue. Maggi Noodles also demonstrates strong revenue performance, while products such as Aashirvaad Atta and Fortune Oil 1L may require further analysis of pricing, discounts, and sales strategy.

Key Findings

The Product Leaderboard by Revenue shows that Coca Cola 1L generates the highest revenue of approximately **₹714,681**, followed by **Maggi Noodles** and **Parle-G**. The comparison with order-based performance indicates that order volume alone does not determine revenue generation. Products such as Britannia Cake and Oreo Biscuits achieve a better revenue position than their order rankings, while **Aashirvaad Atta** shows the opposite trend. These findings can help the business identify high-value products and optimize pricing, promotions, and inventory strategies.

KPI: Average Revenue/Product

Value: ₹5.78 Lakh

Usage: Provides a benchmark for product performance.

Interpretation: Products above ₹5.78 lakh perform above the average.

6. Category-Wise Performance

The **Category-Wise Revenue Share** chart shows the contribution of each product category to the total revenue generated in the dataset. It helps identify the categories that are driving overall business performance.

Key Insights

1. **Snacks is the leading revenue-generating category**, contributing **29.6%** of total revenue. This makes it the most important category in terms of revenue contribution.
2. **Beverages ranks second**, accounting for **21.2%** of total revenue. Its strong contribution indicates consistent customer demand for beverage products.
3. **Grocery contributes 16.5%** of total revenue and ranks third. This shows that essential grocery products form an important part of the business's revenue.
4. The top three categories — **Snacks, Beverages, and Grocery** — **collectively contribute 67.3%** of total revenue. Therefore, nearly **two-thirds of the overall revenue** comes from these three categories.
5. **Instant Food contributes 11.4%** of revenue, placing it fourth. Although smaller than the top three categories, it still represents a meaningful portion of total sales.
6. **Confectionery accounts for 11.2%** of total revenue, showing a similar contribution to Instant Food.
7. **Dairy is the smallest revenue-contributing category**, accounting for only **10.0%** of total revenue. However, the difference between Dairy and Confectionery is relatively small.
8. The distribution indicates that revenue is **not evenly divided among categories**. Snacks alone contributes almost three times as much revenue as Dairy.

Overall Interpretation

The chart clearly shows that **Snacks is the primary revenue driver**, followed by Beverages and Grocery. The strong contribution of these three categories suggests that the business should prioritize **inventory availability, promotions, and marketing efforts** for these categories.

At the same time, the lower contribution of **Dairy, Confectionery, and Instant Food** indicates potential areas for improvement. However, lower revenue share does not necessarily mean poor performance, as these categories may have differences in **product count, pricing, order volume, and discount levels**.

Key Findings

The category-wise analysis shows that Snacks is the largest contributor to total revenue, accounting for **29.6%**, followed by Beverages at **21.2%** and Grocery at **16.5%**. Together, these three categories contribute **67.3%** of total revenue, indicating their significant role in overall business performance. Dairy has the lowest revenue share at 10%. The findings suggest that the business should maintain strong inventory and promotional strategies for high-performing categories while exploring opportunities to improve the contribution of lower-performing categories.

KPI: Top 2 Category Share

Value: 50.9%

Usage: Measures revenue concentration in the two leading categories.

Interpretation: Snacks and Beverages together account for about 50.9% of the displayed category share.

7. City-Wise (Regional) Performance

The **City-Wise Regional Performance** chart compares the total revenue generated across six cities. It helps identify the strongest and weakest-performing geographical markets and highlights where the business has the greatest revenue potential.

Key Insights

- 1. **Hyderabad is the top-performing city**, generating approximately **₹1,250,930** in total revenue. It ranks first and is the strongest regional market in the dataset.
- 2. **Bangalore ranks second** with revenue of approximately **₹1,019,724**. Although it performs below Hyderabad, it still generates more than ₹1 million in revenue.

3. **Pune is the third-highest revenue-generating city**, contributing approximately ₹993,838. Its performance is very close to Bangalore, with a difference of only around ₹25,886.
4. **Delhi generated approximately ₹884,943**, placing it fourth. Its revenue is noticeably lower than the top three cities but still represents a significant contribution.
5. **Chennai generated around ₹834,726**, ranking fifth. The difference between Chennai and Delhi is approximately ₹50,217, showing relatively similar performance between the two markets.
6. **Mumbai is the lowest-performing city by revenue**, generating approximately ₹799,190. Despite ranking last, its revenue remains relatively close to Chennai.
7. The difference between the **highest-performing city (Hyderabad)** and the **lowest-performing city (Mumbai)** is approximately ₹451,740. This indicates a considerable regional performance gap.
8. The **top three cities — Hyderabad, Bangalore, and Pune — generate approximately ₹3.26 million combined**, making them the most important regional markets in the dataset.
9. The chart shows a **gradual decline in revenue from Hyderabad to Mumbai**, rather than an extreme concentration in only one city. This suggests that the business has a reasonably diversified geographical presence.
10. The variation in city revenue may be influenced by factors such as **customer demand, number of product-city records, product availability, pricing, discounts, and purchasing patterns** in each region.

Overall Interpretation

The analysis indicates that **Hyderabad is the strongest regional market**, followed by Bangalore and Pune. The relatively strong performance of these cities suggests that they could be prioritized for **inventory expansion, marketing campaigns, and business growth initiatives**.

Mumbai and Chennai have comparatively lower revenue, but the difference is not extremely large. Therefore, rather than treating them as poor-performing markets, the business could investigate whether **product availability, customer demand, discounts, or regional product mix** are affecting their performance.

It is also important to consider the **number of product-city records in each city** when interpreting this chart. A city with more records naturally has more opportunities to generate revenue, so revenue should ideally be analyzed alongside **orders and record/product coverage** before making expansion decisions.

Key Findings

The city-wise analysis shows that Hyderabad is the leading regional market with total revenue of approximately ₹1.25 million, followed by Bangalore and Pune. The top three cities collectively generate around ₹3.26 million, highlighting their importance to overall business performance. Mumbai records the lowest revenue at approximately ₹0.80 million. Overall, the relatively gradual difference between cities indicates a diversified regional presence, while further analysis of product coverage, orders, pricing, and discounts can help explain the differences in city-wise performance.

KPI: Average Revenue/City

Value: ₹9.64 Lakh

Usage: Provides a benchmark for city performance.

Interpretation: Hyderabad, Bangalore and Pune perform above the average.

The **City-Wise Regional Performance — Orders** chart compares the total number of orders received from six major cities. It helps identify the regions with the highest customer demand and those with relatively lower order activity.

Key Insights

- **Hyderabad leads** with **10,132 orders**, indicating the highest customer demand.
- **Pune ranks second** with **9,638 orders**, closely following Hyderabad.
- **Bangalore** is third with **8,483 orders**, showing strong regional demand.
- **Delhi and Mumbai** have similar order volumes, with **7,779** and **7,560** orders respectively.
- **Chennai has the lowest orders** at **6,854**, but still shows considerable customer activity.
- Overall, **Hyderabad and Pune are the strongest markets**, while Chennai has the greatest scope for improving order volume.

Comparison with Revenue Performance

An interesting observation appears when this chart is compared with the **City-Wise Revenue** chart:

- **Hyderabad ranks first in both orders and revenue**, making it the strongest overall regional market.
- **Pune has the second-highest order volume**, but it ranked third in revenue.
- **Bangalore has fewer orders than Pune but generates more revenue**, suggesting a potentially higher revenue contribution per order.
- **Mumbai has fewer orders than Delhi but also generates lower revenue**, maintaining a similar position across both measures.
- **Chennai has the lowest order volume and also relatively low revenue**, indicating weaker overall regional performance compared with the other cities.

Overall Interpretation

The analysis shows that **Hyderabad is the strongest city in terms of customer order activity**, followed closely by Pune. Bangalore also demonstrates strong demand, while Delhi and Mumbai show moderate performance. Chennai records the lowest number of orders but still maintains considerable activity. The difference between **orders and revenue rankings** is particularly useful because it suggests that **order volume alone does not determine revenue performance**. Factors such as product mix, product prices, discounts, and average order value may influence the revenue generated by each city.

Key Findings

The city-wise order analysis shows that Hyderabad leads with **10,132 orders**, followed by Pune with **9,638** and Bangalore with **8,483 orders**. Chennai records the lowest order volume at 6,854 orders. Hyderabad and Pune emerge as the strongest markets in terms of customer demand, while the relatively close order volumes of Delhi and Mumbai indicate similar market activity. When compared with revenue performance, differences in rankings suggest that factors such as product mix, pricing, discounts, and average order value also influence regional revenue generation.

8. City × Category Demand Matrix

Cross-tabbing revenue by city and category surfaces concentration that city or category totals alone hide:

City	Bev.	Confect.	Dairy	Grocery	Inst. Food	Snacks
Bangalore	1,63,440	1,54,862	64,578	2,13,246	1,21,979	3,01,619
Chennai	1,27,039	62,109	1,17,829	98,411	96,700	3,32,638
Delhi	1,96,117	22,813	66,904	1,03,538	43,546	4,52,025
Hyderabad	3,02,274	1,84,179	1,09,288	2,66,887	1,84,627	2,03,675
Mumbai	2,56,581	1,43,958	68,796	65,752	63,609	2,00,494
Pune	1,81,551	79,503	1,52,253	2,07,519	1,51,016	2,21,996

Key Insights

- **Snacks is the strongest category overall**, with particularly high revenue in **Delhi (₹4.52 lakh)** and **Chennai (₹3.33 lakh)**. This indicates strong customer preference for snack products in these cities.
- **Hyderabad shows the most balanced performance across categories**. It performs strongly in **Beverages (₹3.02 lakh)**, **Grocery (₹2.67 lakh)**, **Confectionery (₹1.84 lakh)**, and **Instant Food (₹1.85 lakh)**, rather than depending on one category.
- **Delhi has a very strong Snacks market**, but its **Confectionery revenue is only ₹22,813**, the lowest value in the entire matrix. This creates a significant category-level gap that could be investigated.
- **Bangalore performs strongly in Snacks (₹3.02 lakh) and Grocery (₹2.13 lakh)**, making these two categories important contributors to its regional revenue.
- **Pune shows strong demand for Grocery (₹2.08 lakh) and Snacks (₹2.22 lakh)**. Its **Dairy revenue of ₹1.52 lakh** is also relatively high compared with most other cities.

- **Chennai is highly concentrated toward Snacks**, with Snacks revenue of ₹3.33 lakh, while Confectionery contributes only ₹62,109. This suggests that customer preferences differ considerably across categories.
- **Mumbai performs particularly well in Beverages (₹2.57 lakh)** but has comparatively lower Grocery revenue (₹65,752), indicating a different category demand pattern from cities such as Hyderabad and Bangalore.
- **Dairy is generally one of the weaker categories**, although Pune (₹1.52 lakh) and Chennai (₹1.18 lakh) show relatively stronger Dairy performance.

Overall Interpretation

The matrix demonstrates that **city-level revenue alone does not explain the complete demand pattern**. Different cities have different category preferences. For example, **Delhi and Chennai are heavily driven by Snacks**, whereas **Hyderabad has a broader and more diversified category performance**.

This information can help the business adopt **city-specific strategies** instead of applying the same marketing and inventory strategy everywhere. High-demand categories should receive sufficient inventory, while weak category-city combinations can be targeted with discounts, promotions, or improved product visibility.

Key Findings

The City × Category analysis shows significant differences in consumer demand across regions. Snacks dominate in Delhi and Chennai, while Hyderabad demonstrates strong and diversified performance across multiple categories. The findings suggest that city-specific product, inventory, and promotional strategies can help maximize revenue and address weaker category markets.

9. Discount Impact Analysis

The dataset uses three discount tiers — 0%, 5%, and 10% — applied roughly evenly across records (107, 91, and 102 rows respectively). Grouping average orders and revenue by discount tier gives a counter-intuitive result:

Key Insights

- **0% discount has the highest average revenue**, approximately ₹21,477 per record.
- At **5% discount**, average revenue falls to around ₹18,634, showing a decline of about **13.2%** compared with 0% discount.
- At **10% discount**, average revenue decreases further to approximately ₹17,545, the lowest among the three discount levels.
- The difference between **0% and 10% discount** is around ₹3,932, indicating that higher discounts are associated with lower average revenue in this dataset.
- The discount levels are fairly evenly represented, so the comparison is not being driven simply by one discount group having far more records.
- The relationship between discount and orders is **very weakly negative**, suggesting that increasing discounts does not necessarily lead to more orders.
- Similarly, the relationship between discount and revenue is **weakly negative**, meaning higher discounts are associated with lower revenue rather than higher revenue in this dataset.

Overall Interpretation

The analysis gives a **counter-intuitive result**: higher discounts do not appear to increase average revenue or order volume. The **0% discount group performs best**, while the 10% discount group has the lowest average revenue.

However, this should be interpreted as a **descriptive finding, not proof of causation**. Other factors such as product type, city, pricing, and demand may influence revenue. Therefore, discounts may simply be more commonly applied to products or situations that already have lower revenue potential.

Key Findings

The analysis shows that average revenue decreases as the discount increases, with 0% discount generating the highest average revenue of ₹21,477 and 10% discount the lowest at ₹17,545. Higher discounts do not appear to generate additional orders or revenue in this dataset. Therefore, discounting should be evaluated carefully and ideally analyzed alongside product, city, and pricing factors before making promotional decisions.

10. Influencer-Marketing Impact

Key Insights

- Only **90 out of 300 records (30%)** have influencer marketing activity marked “Yes”, while **70% of records** have no influencer activity.
- This indicates that influencer marketing was used in a **relatively small portion of the dataset**.
- Records **without influencer activity show higher average orders and revenue** compared with records where influencer activity is present.
- Therefore, in this dataset, **influencer marketing does not appear to be associated with higher sales performance**.
- However, this does **not mean influencer marketing is ineffective**, because the data does not show whether campaigns were specifically targeted toward low-performing products or cities.
- Other factors such as **product category, city, pricing, discount, and campaign timing** may also affect orders and revenue.

Overall Interpretation

The analysis provides a **counter-intuitive result**: products/records without influencer marketing activity perform better on average than those with influencer activity. This could mean that influencer campaigns were not generating additional demand, **or** that campaigns were being used for products or regions that already had lower baseline demand.

Therefore, the result should be treated as a **descriptive observation rather than a causal conclusion**. A proper before-and-after or controlled comparison would be needed to determine the actual impact of influencer campaigns.

Key Findings

Only **30%** of records involve influencer marketing, while **70%** have no influencer activity. Surprisingly, records without influencer activity show higher average orders and revenue. This suggests that influencer marketing is not clearly driving additional sales in the current dataset, but further controlled analysis is required before concluding that the campaigns are ineffective.

11. Pricing & Average Order Value (AOV) Analysis

Current Price correlates strongly with Original Price ($r \approx 0.99$) and moderately with Revenue ($r \approx 0.67$), but has almost no correlation with Orders ($r \approx 0.01$) — i.e., in this dataset, higher-priced items are not ordered meaningfully less often than lower-priced ones, and revenue is driven more by which product/category is being sold than by price alone.

Average revenue-per-order (AOV) by category:

Key Insights

- **Confectionery has the highest AOV** at approximately **₹123 per order**, indicating that customers spend more per order in this category.
- **Snacks rank second** with an AOV of around **₹119**, showing strong basket value along with high order frequency.
- **Dairy and Instant Food** have similar AOVs of approximately **₹118** and **₹117**, respectively.
- **Beverages** have an AOV of around **₹114**, which is moderate compared with the other categories.
- **Grocery has the lowest AOV** at approximately **₹101**, suggesting that grocery orders are generally lower-value but may occur more frequently.
- The difference between the highest AOV (**Confectionery ₹123**) and lowest AOV (**Grocery ₹101**) is about **₹22**, showing noticeable variation in customer spending across categories.
- **Current Price and Original Price have a very strong correlation ($r \approx 0.99$)**, indicating that products with higher original prices generally also have higher current prices.
- Current Price has a **moderate positive relationship with Revenue ($r \approx 0.67$)**, suggesting that pricing contributes to revenue, although it is not the only factor.
- The relationship between **Current Price and Orders is almost zero ($r \approx 0.01$)**, indicating that higher-priced products are not necessarily ordered less frequently.

Overall Interpretation

The analysis shows that **AOV varies by category**. Confectionery and Dairy generate higher revenue per order, making them potentially useful for **cross-selling and bundling** with high-frequency categories such as Snacks and Beverages.

On the other hand, Grocery has the lowest AOV. This may be because grocery products such as **atta and oil are frequently purchased essentials with relatively lower basket values**. Their lower AOV does not necessarily indicate weak demand.

The correlation analysis also suggests that **price alone does not determine order volume**. Customers may continue purchasing higher-priced products when they have strong demand or are essential items.

Key Findings

The AOV analysis shows that Confectionery has the **highest average order value at ₹123**, while Grocery has the **lowest at ₹101**. Pricing has a moderate relationship with revenue but almost no relationship with order volume. This indicates that category, product demand, and purchasing behavior play an important role alongside price in determining sales performance.

12. Top & Bottom Performing Product–City Pairs

Top 5 by Orders

Product	City	Discount (%)	Orders	Revenue (₹)
Coca Cola 1L	Hyderabad	5	299	54,418
Parle-G	Chennai	10	299	30,199
Fortune Oil 1L	Bangalore	10	299	45,747
Coca Cola 1L	Mumbai	5	297	32,373
Nestle Munch	Bangalore	10	297	58,212

Product	City	Discount (%)	Orders	Revenue (₹)
Nestle Munch	Hyderabad	5	50	4,100
Britannia Cake	Pune	0	52	10,036
Parle-G	Pune	0	52	8,112
Fortune Oil 1L	Pune	10	52	7,124
Pepsi 500ml	Chennai	10	52	3,276

Bottom 5 by Orders

Overall Interpretation

The analysis shows a clear difference between the **highest- and lowest-performing product-city combinations**. The top-performing pairs record around **297–299 orders**, with Coca Cola 1L in Hyderabad and Parle-G in Chennai reaching 299 orders. In contrast, the weakest pair, **Nestle Munch in Hyderabad**, records only **50 orders** and ₹4,100 revenue. The results indicate that product performance can vary significantly depending on the city, even for the same product. Discounts also vary across these combinations, suggesting that **location, product demand, and pricing/discount strategies** may influence performance.

Key Findings

The Top & Bottom Product-City analysis highlights significant variations in demand across different locations. High-performing combinations can be prioritized for inventory and marketing, while low-performing pairs should be further investigated for factors such as customer demand, pricing, discounts, and product availability. This city-specific analysis can help the business develop more targeted sales strategies..

13. Data Quality Notes & Limitations

- No date/time field: every 'trend' or 'growth' question a real Zepto analytics stack would ask (day-over-day, week-over-week, seasonality) cannot be answered from this dataset — all findings above are same-period, cross-sectional comparisons.
- Current Price vs. Original Price: in 220 of 300 rows, Current Price is higher than Original Price, and in the remaining 80 rows the two are equal — Current Price is never lower than Original Price anywhere in the dataset. This means the 'Discount' column does not behave as a price reduction relative to Current Price the way a typical discount field would; it should be treated as a labeled campaign/discount-tier attribute rather than as $(\text{Original} - \text{Current})/\text{Original}$ in its literal sense.
- Record-count imbalance: cities and products don't have equal numbers of rows (e.g., Hyderabad has 60 rows vs. Chennai's 42; Maggi Noodles has 36 rows vs. Oreo Biscuits' 23), so raw totals in Sections 5, 6 and 8 partly reflect data coverage, not demand alone — per-record averages are provided alongside totals for this reason.
- No user-level or repeat-purchase data: the dataset is pre-aggregated at product-city level, so cohort, retention, and repeat-order-rate questions are out of scope for this report.
- Influencer and discount findings in Sections 10–11 are descriptive correlations only, not controlled experiments — no causal claim is made about whether discounting or influencer activity drives orders.

14. Summary of Key Metrics

Metric	Value
Total Orders	50,446
Total Revenue	₹57,83,351
Blended AOV (Revenue/Order)	₹114.64
Average Discount	4.92%
Top Category (Revenue)	Snacks — ₹17.12L
Top City (Revenue)	Hyderabad — ₹12.51L

Metric	Value
Top Product (Orders)	Coca Cola 1L — 6,175
Records with Influencer Activity	90 / 300 (30%)
Discount ↔ Orders correlation	≈ -0.03 (negligible/weak negative)
Price ↔ Orders correlation	≈ 0.01 (negligible)

15. Descriptive → Predictive: Suggested Next Steps

Based on the Zepto sales analysis, the descriptive findings can be used for predictive analytics in the following ways:

- **Sales & Revenue Forecasting:** Use past sales and revenue data to predict future sales trends and identify expected high- and low-sales periods.
- **Product Demand Prediction:** Predict which products are likely to receive more orders so that popular products can be kept sufficiently in stock.
- **Discount Optimization:** Analyze the impact of different discount levels on orders and revenue to determine the most effective discount strategy.
- **City-Wise Demand Forecasting:** Predict future demand for different cities and allocate inventory and delivery resources accordingly.
- **Inventory Planning:** Forecast product demand to reduce **stock-outs and excess inventory**, improving overall operational efficiency.
- **Influencer Marketing Prediction:** Predict whether influencer campaigns can increase orders or revenue and identify where such campaigns are most effective.
- **AOV Prediction:** Use pricing, category, and order patterns to predict and improve **Average Order Value (AOV)** through bundles and cross-selling.

Suggested techniques: Regression, Random Forest, XGBoost, Time-Series Forecasting (ARIMA/Prophet), and K-Means Clustering.

Appendix: Glossary

- **AOV** — Average Order Value; here calculated as Total Revenue ÷ Total Orders for a given cut of the data.
- **GMV** — Gross Merchandise Value; total value of goods sold, before any platform fees.
- **SKU** — Stock Keeping Unit; an individual product (e.g., 'Coca Cola 1L').
- **Correlation (r)** — a statistical measure between -1 and 1 of how strongly two variables move together; values near 0 indicate little to no linear relationship.
